Abstract

Introducing a healthy lifestyle among young adults enrolled at higher learning institutions via health promotion is best to improve health. This study investigates the effects of lifestyle modification intervention programs (LMIP) on perceived benefit-barrier behaviour, self-efficacy, health-promoting lifestyle behaviour, and MetS parameter. This two-phase study: cross-sectional and two-arm randomized controlled trial involved 124 young adults who full-fill the criteria randomly assigned either intervention or control groups. The intervention group will receive LMIP, while the controlled group will receive an information booklet. Data collection will be collected at four-time points and analyzed using a mixed-design analysis of variance (ANOVA).

Keywords: young adult, cardiovascular diseases, physical activity, diet

1.0 Introduction

Metabolic syndrome (MetS) significantly increases the risk of developing non-communicable diseases (NCDs), mainly cardiovascular diseases (CVDs), due to the presence of dyslipidemia, hyperglycemia, and hypertension. MetS associated with NCDs prevalence are increasing globally (Sakalyan, 2018), and Malaysia has become the second country in the pacific region with the highest prevalence of MetS (37.1%) (Ranasinghe et al., 2017). Mets is a disorder of energy utilization and storage reflecting underlying insulin resistance. It is characterized by at least three of the following five risk factors: abdominal obesity, high blood pressure, raised fasting blood sugar, high serum triglycerides, and low high-density lipoprotein cholesterol (HDL-C) (WHO, 2010). The latter two is an abnormality that occurs in the blood cholesterol value known as dyslipidemia.

Cholesterol is a structural component of the plasma membrane, and it is essential for life and has many roles that contribute to normally functioning cells (Huff, Bod & Jiala, 2020). Therefore, in almost every country, identifying and treating dyslipidemia most of the time will be done among older adults over 40 years old. Dyslipidemia in young adults is prone to develop risk factors for atherosclerosis and may contribute to coronary heart disease in their future adulthood (Haney et al., 2007). Identifying and preventing the affected youths may reduce long-term cholesterol-related disorders.
through intervention. Among the general population, young adults who are enrolled in high learning institutions (HLI) are considered high-risk populations to adopt unhealthy lifestyles due to changes in their study mode and experience of an independent life away from their parents or guidance. Moreover, the young age student may assume that they are in good health and not pay much attention to their future health problem. So, investigating young adults among the HLI student’s awareness and behaviour towards a healthy lifestyle may be considered a priority for preventive efforts and management of MetS. As its prevalence increases dramatically with age, identifying and managing its contributing factors has become more prudent. MetS are also known as a complex multifactorial trait that was influenced not just by biological, genetic factors but also by the environment, including lifestyle. Considering the multi-modal approach to managing MetS does not appear to be modifying the subject of non-pharmacological therapy in terms of lifestyle modification such as healthy diet and physical activity. It was suggested that primary intervention is holistic, cost-effective, and increases life quality (Saboya et al., 2016). Health promotion is the best option to improve health by introducing healthy lifestyles and habits to achieve this outcome.

The concept of health promotion is to promote a greater awareness of the positivity towards health by targeting specific populations or communities to develop their skill and knowledge to understand and prevent the forming of other illnesses and accelerate their development (WHO, 2019). However, there is still limited evidence to support the effectiveness of health promotion lifestyle intervention among the young adult population enrolled in HLI to prevent and manage MetS risk factors.

This study aims to assess the level of knowledge and awareness of MetS, health-perceived behaviour, self-efficacy, and health-promoting lifestyle behaviour among young adults, especially those who are HLI’s students. This study also aims to evaluate the pre-and post-effects of health-promoting lifestyle modification intervention programs on blood cholesterol level, body mass index, and MetS parameter for preventing and managing Mets as a risk factor of developing CVDs.

2.0 Literature Review

Mets are considered a major complex public health issue due to the associated risk for developing Type 2 Diabetes Mellitus (T2DM) and cardiovascular diseases (CVDs) (Monnerie et al., 2020), which contribute significantly to the burden of disease worldwide (Solomon & Mulugeta, 2019). Dyslipidemia is regarded as a hallmark of MetS, and over the past five years, the trend of dyslipidemia among Malaysian adults has increased. A previous study reported that 35.1% of adults aged above 18 years old had high blood cholesterol levels. However, almost half of the number do not become aware of their blood cholesterol status (Rifin et al., 2018). Adequate literacy levels and awareness are essential as they will lead to a successful education program. The individual will have the capacity to understand basic health information, make appropriate health decisions, and engage in health behaviour maintenance in the future. Dyslipidemia affects all stages of the population. Therefore, it is vital to observe trends in different life cycle phases, especially among young adults in HLI such as college or university.

A previous study on the impact of academic exposure on the health status of university students by Brandao and colleagues (2011) showed a higher rate of dyslipidemia when a trend of total cholesterol and lower (LDL) cholesterol reported an increase in value between academic exposure versus non-academic exposure student (48% versus 28.6%) respectively. A study investigated on risk behaviour of CVDs towards college students around ASEAN countries showed a high prevalence of overweight, low physical activity, tobacco use, binge drinking, and non-avoidance of fat and cholesterol into their meal (Peltzer & Pengpid, 2018). In Malaysia, previous studies showed that college or university students were not keen on performing the exercise as 10-58% of their respondents rarely or never did the physical activity (Ibrahim, Rahman & Rahman, 2016).

2.1 Health-promotion Intervention of Lifestyle Behavior

Lifestyle, by definition, is in the way of living, while a healthy lifestyle is a way of living that lowers the risk of being seriously ill or dying at an early age (WHO, 1999). In many deaths, some diseases are preventable and can be avoided, such as coronary heart disease. However, health is not just about preventing illness but also about physical, mental and social well-being. When a healthy lifestyle is adopted, a more positive role model is provided for other people. "By the year 2015, people across society should adopt healthier living patterns" this phrase was adopted from European Health Target by the WHO Regional Committee for European in September 1998. Five years ahead by the target year, NCDs had become the number one killer of the population worldwide. CVDs still chart the highest causes of death among the clinical patient due to modifiable risk factors of health behaviour as the significant causes.

Health practitioners who have traditionally concentrated on disease treatment are increasingly concerned with preventing and providing health through promoting lifestyles and removing the factors that have a detrimental effect on human health in every way (Tol et al., 2016). Health promotion is an approach taken to direct people in the acquisition of physical fitness and general well-being. This method of promotion aims to guide individuals to become self-actualized through growing encouragement to participate in health promotion behaviours concerning their human health potential (Walker, Schrist, & Pender, 1987). When contemplating a personal involvement in health promotion lifestyle, these six domains need to be considered; 1) Nutrition; 2) Physical activity; 3) health responsibility; 4) spiritual growth; 5) Health responsibility, and 6) Stress management (Pander, Murdough & Parsons, 2010). Health promotion lifestyle is a multi-dimensional pattern of self-motivated attitudes and behaviours that lead to maintaining and promoting their health and self-improvement (Walker et al., 1996). A past study conducted in Iran among university students revealed a statistically significant relationship between life quality and spirituality. However, there was no significant relationship between life quality and nutrition, physical activity, self-health responsibility and stress management (Tol et al., 2016). A similar finding was reported from a study related to health-promoting lifestyle among nursing students in Malaysia. The highest score was revealed in spiritual growth, and physical
activity was the lowest (Geok et al., 2014). Table 1 below summarises the previous studies on the effect of a health-promoting behaviour and lifestyle intervention.

In general, for individuals to change their behaviour towards a healthy lifestyle, they must understand the benefit of a healthy lifestyle and identify the barrier and their capability to engage and enhance the behaviour changes. Guidance would have to be given to set a clear, realistic and achievable target for the expected good outcome following the desired period. Health-promotion lifestyle intervention plays a vital role to achieve the highest possible health outcome to reduce the prevalence of non-communicable diseases, especially CVDs in the future.

3.0 Methodology

The current study will involve Phase 1 as a cross-sectional baseline data collection and Phase 2, an intervention phase for randomized control trial (RCT) to investigate the pre-and post-intervention effects of health-promoting lifestyle modification intervention program.

Phase 1

This phase will be involved a quantitative descriptive and cross-sectional study. This phase aims to assess the knowledge and awareness of MetS among HLI students and identify the relationship between socio-demographic factors, perceived barrier-benefit behavior, and self-efficacy with health-promoting lifestyle behavior among HLI students. The finding from this phase will provide valuable information. It will help organize the health-promoting lifestyle intervention program during phase 2 to deliver effective interventions for the prevention of MetS. An online self-administered questionnaire, anthropometric measurement, and rapid test assessment for blood
Cholesterol level investigation will be performed. One stage cluster random sampling will be applied in this phase to select the study location with eligibility criteria were used in this study. The results data from this phase will be used to design the program for intervention in phase 2.

**Phase 2**

To address the objectives of the research, a randomized control trial (RCT) will be conducted within 12-week of a health-promoting lifestyle modification intervention program with a pre-and post-test double-arm design (intervention and control group) among young adults who are enrolling at HLI. The group allocation will be determined randomly where the two groups will be allocated to either intervention or control with a probability of 0.5 (Campbell & Walters, 2014). The participants will be analyzed based on the intention-to-treat principle to maintain reliability and internal validity and prevent randomization errors. This phase is a single-blinded study where only the researcher knew the group allocation (intervention or control). The researcher-supported team (e.g., research assistant, statistician) or others involved in this study will be unaware of group assignment. The intervention group participants will be followed the intervention program for 12 weeks, completed questionnaires and underwent repeated assessment pre-and post-intervention. The measurement will be conducted at baseline, week-4 (1st follow-up), week-8 (2nd follow-up), and week-12 (evaluation). Simultaneously, the control group will be receiving an information booklet related management of MetS (adopted from the Malaysia Ministry of Health) and will be undergone with the same assessment and measurement. After completing the study, the control group will be offered to receive the same program as the intervention group. Simple random sampling will be carried out for participant selection. The eligible participants who participate in Phase 1 will be chosen, and they had an equal chance of being included in the sample. The randomization of participants into the group will be done using Research Randomizer by Urbaniaik and Pious (2013) from a website www.randomizer.org.

**3.1 Research Instrument**

**Questionnaire assessment tools**

The questionnaire assessment tools will be consisting of 1) Socio-demographic data; 2) Assessment of knowledge and awareness towards MetS; 3) Assessment of perceived barrier-benefit behavior; 4) Self-efficacy measurement; 5) Assessment of health-promoting lifestyle behaviours. An online self-administered questionnaire in the English version will be provided through survey software using the SurveyMonkey.com.

**Intervention Measurement Tools**

During four time-points: at baseline, week-4, week-8, and week-12 of the program, all the selected participants will be undergone for 1) Anthropometric measurement; 2) Blood pressure measurement and 3) Blood sample collection for Fasting Lipid Profile and Fasting Blood Sugar.

**3.2 Intervention Program Module**

The lifestyle modification intervention (LMI) program module will be following the Health Promotion Model framework by Nola Pender (1996) and Albert Bandura’s self-efficacy theories (1997). The LMI knowledge platform is a construct of the health promotion model regarding prior related behavior and personal factors, behavior-specific cognition, and effects which are concluded of perceived benefits-barrier behavior, perceived self-efficacy, and affect cues to behavior. Within the framework of the health promotion model, the education session will be included a brief introduction of MetS and its management, assessment of current behavior and behavior-specific cognition, providing personalized advice regarding healthy diet, regular exercise, stress management, and self-monitoring, also constructing a plan to make modification behavior. The intervention will be focusing on increasing the participant's cognition for adopting health-promoting behaviors. At the same time, self-efficacy is a key behavior-specific cognitive factor contributing to implementing health-promoting behaviors. To enhance participants' self-efficacy, they will be encouraged to develop their target, work in small, realistic steps, focus on their attention, and set the confidence to perform the desired behavior.

The intervention will provide detailed knowledge related to MetS and practical strategies to implement health-promoting behaviors in daily life. The intervention will be consisted: 1) individualized in-person education, 2) grouping activity, 3) a lifestyle modification intervention e-booklet including exercise tools and 4) virtual follow-up. The LMI program will be developed through intensive literature review and following the guideline from the 5th edition of Clinical Practices Guideline for Management of Dyslipidemia 2017 (Ministry of Health (MOH)). The National Cholesterol Education Program Adult Treatment Panel III (NCEP ATP III), 2019 European Society of Cardiology (ESC) and European Atherosclerosis Society (EAS) of The Task Force for management of dyslipidemia and WHO for Prevention of CVD. The completed LMI module for appropriateness and relevance of content will be evaluated by the panel of experts and the content validation will be using an adapted content validation form proposed by Castro and colleagues (2007).

**3.3 Data Collection Process**

After ethical approval by UiTM Research Ethics Committee, permission will be obtained from the selected HLI’s authorities to recruit the participants.
Phase 1
The potential participants will be recruited and invited to complete an online questionnaire administered using the official online survey questionnaire. Those who completed the survey will be invited to a specific venue located in their institution for anthropometric measurement, blood pressure, and blood sample investigation (to refer Figure 1).

Phase 2
Verbal and written consent will be obtained from the participants in harmony with the Helsinki declaration, and the details of the study will be explained. The data will be collected during pre- and post-intervention of 12-week health promoting lifestyle modification behavior. The data collection method will be divided into three phases: pre-intervention (baseline assessment), intervention and post-intervention (final assessment). Follow-up will be added as an additional phase and will be conducted one month after intervention completion (to refer Figure 2).

3.4 Data Analysis
According to their group assignment, the participants will be analyzed based on the intention-to-treat principle to provide an unbiased estimate of the intervention’s efficacy, maintain reliability and validity, and prevent randomization error (McCoy, 2017).

Phase 1
Descriptive statistics will be used to summarize participants' health and demographic characteristics. Self-administered questionnaire will be analyzing using Chi-square for categorical variables while continuous variables will be assessed using Pearson Correlation Coefficient, independent t-test and Analysis of Variance (ANOVA) (for normal distribution of data) as appropriate. A p values <0.05 will be considered as statistically significant.

Phase 2
Data will be coded and analyzed using SPSS version 24.0. Comparisons between the intervention group and the control group will be performed using univariate and multivariable methods. Outcome variables at baseline and 3 months post-test will be used to test the hypotheses in association with the covariates and confounding variables. To evaluate effects in each group, repeated measure Analysis of Variance (ANOVA) will be used. Mixed design ANOVA will be performed to determine the effects between the groups. The significance level for all analyses was set at p<0.05.

Expected outcome/ Summary
The finding of this study may indicate the development of new conceptual framework related to lifestyle behaviour intervention on management of metabolic syndrome among tertiary education population in order to prevent and reduce the prevalence of cardiovascular risk factor in the future. Furthermore, a new lifestyle modification intervention program by mean of an all-inclusive perspective and holistic nature as the finding will make it an accommodating approach related lifestyle behaviour of higher education population in order to manage metabolic syndrome generally among young adult with potential to reduce the risk to develop non-communicable disease. In addition, this fundamental of this study will provide as a novel material that can be used as a guideline and references to the health-care provider with MetS issue. It also can be as new findings or references for the Asian and international health care practices.

Acknowledgement
Authors would like to thank Institute of Research Management Center (RMC) of Universiti Teknologi MARA for funding the research. Grant No: 600-RMC/GPK 5/3 (064/2020)

Paper Contribution to Related Field of Study
This study can promote an optimize healthy lifestyle behavior among young adults and potentially contribute to programs and policies guideline to reduce the risk of developing non-communicable diseases in the future. The finding from this study will create awareness among young adults regarding dyslipidemia and MetS as risk factors in developing CVDs by increasing knowledge, confidence and skills in order to develop longevity habit and promote health behavior towards healthy lifestyle. As been mention before, the field of the study still not been covered in depth and not fully explored in Malaysia. Hence, the finding from this study will provide novel material and baseline information to improve the guideline and management performance especially among the target population. The information from the finding of this study may also contribute as baseline information for the ministry and provide a medium especially for nursing profession in delivering an optimum health promotion and expand professional scope into preventive measured intervention across the population.
Ethics approved by the UiTM Research Ethic Committee

Permission for data collection granted by the in-charge authorities of each listed higher learning institution

**Inclusion criteria**
- Aged between 18-25 years old
- BMI more than 25 or meet one of five MetS criteria by NCEP ATP III
- Engaged in exercise less than two times per week
- Have family history with cardiovascular disease

**Exclusion criteria**
- Experiencing severe knee pain or musculoskeletal injury
- Diagnose with NCDs
- Congenital disorder
- Surgical history for the past 6 months
- History of hospitalization in the past 3 months
- Involve in others similar research study

**Shortlist students based on inclusion & exclusion criteria**

**Explain objective**

**Access to self-administered on-line questionnaires**

**Consented**
- Obtain informed consent

**Not Consented**
- Excluded

**Answer all questionnaires and submit the respond**

**Submit**

- Anthropometric measurement
- Blood pressure
- Blood sample collection

**Record and analysed data using IBM SPSS Statistic Version 26**

**Questionnaires**
- Part A: Socio-Demographic
- Part B: Knowledge and awareness of MetS
- Part C: EBBSS
- Part D: SRAHP
- Part E: HPLP-II
